## What Does the Checklist Tell Me?

---

**So, you knew it all...**

If you checked off ALL of the items on this list, then you probably have the skills and knowledge for any job that requires passing the basic electricity test. We still recommend that you take the practice test in Section 3. If you do well on the practice test, then you should sign up for the actual test.

---

**So, you knew most of it...**

If you checked off most of the items on the list, you should concentrate on what you DID NOT check off. Buy or borrow one of the resource books listed in Section 4, Page 8 and review it to see if it answers your questions. If you feel that your self-study session brought your skills up to par, take the practice test. If you do well on the practice test, then you should sign up for the actual test.

---

**So, you only know some of the topics...**

You probably need some additional training and education even before you take the practice test. If you're a regular full-time or regular part-time employee with at least six months of seniority, you are to participate in services offered through Employment Security PARTNERSHIP and should look at Appendix A for options. If you're not eligible for such training, then look at Appendix B for information about obtaining further education outside of BellSouth.

## Section 2—Test Description

---

## The Basic Electricity Test

---

**What is the purpose of the Basic Electricity Test?**

To measure your knowledge and ability to apply concepts, terms, and principles involved in working on or near electrical equipment. Although the test contains some factual questions, it emphasizes your understanding of the subject and your ability to apply what you know, not just your memory for facts or formulas.

---

**Who has to take it?**

Candidates for certain BellSouth technical jobs are required to qualify on this test. Although there are no prerequisites for taking the Basic Electricity Test, without prior training or work experience in basic electricity, you probably will not do well on the test.

---

**What kind of test is it?**

It is a 60-question multiple choice test. Each question has 4 possible answers to choose from (a, b, c, d). Some questions refer to figures containing circuit diagrams or other schematics. These will be provided to you in a printed Reference Booklet.

---

**How do I take the test?**

In most locations, the test is given on a PC. Questions appear on the screen like this:

- Q: What is a “short”?

  - a. an inductor that uses no power
  - b. an interrupted circuit
  - c. an undesired conductive path in a circuit
  - d. a bare conductor

(Next Question)

Just touch the screen to indicate the answer you think is correct, answer “c” in the sample question above. When you’re ready for the next question, you press “Next Question” at the bottom of the screen. You can change your answers as many times as you wish, go back to an earlier question, or review the entire test. You will have 60 minutes to finish.

---

*Continued on next page*

---

## The Basic Electricity Test, Continued

---

**Will I have to do any calculations?**

Yes, but you can use a calculator. You will be required to bring a calculator that is silent, handheld, and battery operated. It cannot be solar or have alpha characters on the keypad. The calculator you bring should be able to perform the following functions: Addition, Subtraction, Multiplication, and Division.

---

**Do I have to remember formulas?**

You will use formulas on the test, but you don't need to have them memorized. The Reference Booklet, which contains the figures, also lists all the formulas you might need. You can refer to it any time your memory needs jogging.

---

**How is my score determined?**

Your score will be the number of questions you answer correctly. There's no penalty for guessing, so try to answer every question.

---

**What happens if I don't pass?**

If you take the test but do not score high enough to qualify, you will have to **wait for at least six months before taking the test again.**

We strongly encourage you to use the practice test to evaluate your potential for passing the actual test. If you score poorly or are weak in certain areas, you should seek additional training or self-guided study **before** taking the Basic Electricity Test.

<b>10.</b>	c	<b>20.</b>	a		

2. Count the number of questions you answered correctly. This is your total score.
3. Make a list of the questions you missed or got right but were unsure of. Review the explanation of those questions on the following pages.

---

## Explanation of Practice Test Questions

---

**1-a** The larger the cross-sectional area of a wire, the greater the number of electrons it can carry. The American Wire Gauge (AWG) system provides guidelines on wire characteristics. The smaller the value of AWG, the greater the cross-sectional area of the wire. The **9 AWG** wire will have the greatest cross-sectional area of any of the choices.

---

**2-c** Electrical pressure is the push given to electrons that causes them to flow through circuits. The unit of measure for electrical pressure is the **volt**.

---

**3-a** In a series circuit, the current is equal at each point in the circuit and voltage is divided among the circuit components. In a **parallel** circuit, the voltage across each component is the same and the current is divided among the separate branches.

---

**4-c** Increasing temperatures cause electrons to be more active. The random nature of the increased activity causes collisions between thermally excited electrons and current carrying electrons. The collisions tend to disrupt the flow of electrons through the circuit. This disruption **reduces the net current flow**.

---

**5-b** Resistive elements in a circuit dissipate energy in the form of heat. Resistors connected in series are added to get total resistance. The power formula  $P = IE$  is used to determine the power used. First, use Ohm's law to find the current (I).

$$\Rightarrow I = E/R = 50/135 = .37 \text{ amps}$$

The power dissipated in heat can then be found using the power formula:

$$\Rightarrow P = IE = .37 * 50 = \mathbf{18.5 \text{ watts}}$$

---

*Continued on next page*

## Explanation of Practice Test Questions, Continued

---

**6-b** Because the voltage drop across each component of a parallel circuit is the same, Ohm's law can be used to find the current in each branch. The total current is then found by adding the current in each branch. Since in this case, the branches have equal resistance, simply find the current in one branch and multiply by the number of branches.

- Current in one branch:  $I = E/R = 10/30 = .333$  amps per branch
  - Total current of the parallel circuit:  $.333 \text{ amps} * 2 \text{ branches} = .67$  amps
- 

**7-a** The total power consumed in any circuit is a function of the power formula:

- Power = current (I) times voltage (E) or  $P = IE$
- 

**8-a** According to Ohm's law,  $I = E/R$ , current has an inverse relationship with resistance. As resistance (R) decreases, current (I) increases.

---

**9-c** Use the power formula,  $P = IE$ , to find this answer. Solving for E:

- $E = P/I = 10/.5 = 20W$ .
- 

**10-c** The symbol for an energy source, in this case a battery, is symbol I.

---

*Continued on next page*

---

## Explanation of Practice Test Questions, Continued

---

**11-c** In a reactive circuit, the higher value of reactance will determine whether the circuit is capacitive or inductive. Here, the capacitive reactance is higher than the inductive reactance. Therefore, the circuit is capacitive.

---

**12-d** Electricity delivered to a wall outlet is stated in terms of rms voltage. A standard multimeter provides a reading of AC voltage in terms of rms.

---

**13-b** When a DC voltage is applied across a capacitor, there will be an initial flow of current. As the voltage across the capacitor charges up to the value of the source voltage, current flow will slowly decline. At the point where the voltage is approximately equal, all current in this circuit will stop flowing because there is no difference of potential.

---

**14-d** A capacitor is a device that stores electrical energy.

---

**15-c** Capacitors in parallel are measured like resistors in series. Add the three capacitors to get the total capacitance of the circuit.

- $15 \text{ pF} + 30 \text{ pF} + 60 \text{ pF} = 105 \text{ pF}$
- 

*Continued on next page*

## Explanation of Practice Test Questions, Continued

---

**16-a** The value of a capacitor (capacitance) can be increased by increasing the surface area of the plates, increasing the value of the dielectric constant, or decreasing the distance between the plates.

---

**17-b** Magnetic flux is created as alternating current changes direction and causes lines of flux to vary in the magnetic field. As the lines of flux vary, they cause current to flow in nearby conductors.

---

**18-d** The Henry is a unit of measure for **induction**.

---

**19-c** **Ohmmeters** are used for testing continuity. Inductor windings are usually coils of wire and if not broken, can be tested with an ohmmeter for continuity.

---

**20-a** MOVs react very quickly to **over-voltage conditions**. When the voltage threshold of a MOV is exceeded, it instantly acts as a conductor, shorting the transient spike to ground. MOVs are commonly used to protect equipment that is attached to a transmission line.

---

*Continued on next page*

---

## Explanation of Practice Test Questions, Continued

---

**21-b** A fuse responds to an over-current condition by opening. This separates the source from the circuit in the event of an overload. Therefore it should be connected so that it is between the source of energy and the circuit—**in series with the load**.

---

**22-d** A circuit designed to work with 30 volts at 6 amps has a load resistance of 5  $\Omega$  (Ohm's law). If the load resistance drops to 2  $\Omega$ , the circuit current will increase to 15 amps (Ohm's law) if there is no way to stop it. If the protection device (see question 21) works properly, it will **open** a circuit if current goes beyond its designed current carrying ability.

---

**23-b** 100 microwatts =  $100 * 10^{-6}$  watts = .0001 watts = **0.1 milliwatts**.

---

**24-a** Voltmeters measure **difference of potential** in electrical circuits.

---

**25-c** **Polarity** is of major importance in direct current circuits. Voltmeters are sensitive to polarity when making measurements in DC circuits. Correct placement of leads is very important when making these kinds of measurements.

## Interpreting Your Test Score

**How Did I Do?** The Practice Test questions are very similar to—but not the same as—the questions you’ll see on the real test. Your Practice Test score will give you a good idea of how well you could expect to do on the real test but, of course, only your score on the real test counts.

Find your score level in the table below to get a good idea of how well prepared for the test you are right now.

**Table 3.1** Use the following table to interpret your score.

<b>If your Practice Test score was . . .</b>	<b>then . . .</b>
20 – 25	Congratulations! You are ready to take the real test and should have an excellent chance of qualifying. <b><i>Get ready for the test</i></b> with the help of the hints in Section 4.
15 – 19	You did pretty well but are probably a little rusty in some areas. If you took the real test now, you would have fair chance of qualifying. You can improve the odds if you <b><i>review your weak areas</i></b> first. See Section 4.
10 – 14	Although you know some of the material, your score indicates that there are some subjects that you’ve never studied or haven’t worked with in quite a while. Use Section 4 to <b><i>plan a study strategy</i></b> .
0 – 9	You do not know the material well enough to prepare on your own. If you’re still interested in taking the test, <b><i>take a course</i></b> . Find out what to look for in Section 4.

## Section 4—Educational & Training Resources

---

## Evaluating Your Needs

---

### **Studying on your own**

If you did well on the practice test (15 or higher), but you still want to brush up on your skills, try studying the material on your own.

- Identify your weak areas
- Find a textbook or manual (there is a list on page 8)
- Study

Check your progress and evaluate if you need more help.

---

### **Correspondence Courses**

If you scored in the mid-teens on the practice test and feel that you need guidance with studying, then a correspondence course can be a flexible and efficient way to further your education. There are several options:

- Paper-based courses
  - Computer or web-based courses
- 

### **Classroom Training**

If you scored in the low teens or lower on the practice test, you would be well-served to take a course that offers professional instruction and testing. Sources are found in Appendix A (for eligible regular full-time or regular part-time employees) and Appendix B (for candidates who are not eligible employees)

---

### **Math Skills**

Don't forget the math and calculator skills because you'll need them right away.

If you don't know how to solve simple equations or work confidently with negative numbers and decimals, get these skills first. You can either:

- Find a math review book and brush up on your own, perhaps with the help of a friend; or
- take an applied math course; or
- choose an electricity course that includes a math module at the beginning.

If you know the math basics, you can probably start right in with a basic electricity course.

---

## Appendix A: Training Options for Eligible Employees

---

**What is an eligible employee?**

All regular full-time and regular part-time employees with at least six months of seniority are eligible to participate in services offered through the Employment Security PARTNERSHIP. In many cases, these services are offered to eligible employees at no cost.

---

**What are my options?**

Based on your individual skills and needs, you can select from any of the following options:

- Correspondence courses;
  - A computer-based course; or
- Classes from your local school or community college.
- 

**Keep in Mind:**

Participation in these classes should enhance the learning of skills and knowledge required for specific jobs. However, **taking a course does not always guarantee that the candidate will qualify** for the job title they are seeking.

---

## Correspondence Courses for Eligible Employees

---

### Introduction

The Correspondence Course Program is administered through the Employment Security PARTNERSHIP. Although this method allows more flexibility than traditional school attendance, the courses still require a fair amount of time and motivation. Systematic study, conscientious application and a high degree of self-discipline are basic requirements of each course.

There are two courses that might apply:

- CT100: Basic Mathematics Review
  - CT208: Basic Electricity
-

## Vocational Classes

---

### Introduction

A classroom-based course offered by a technical school, two-year or four-year college and taught by an experienced instructor is one good choice for training, particularly if you are new to electricity. Compare the checklist of required knowledge and skills from Section 2 to the course curriculum. If you're unsure whether a certain course covers what you need, ask someone at the institution offering the course, preferably the instructor. You may wish to share the checklist with a knowledgeable person at the institution.
